

# CPE 325: Intro to Embedded Computer System

## Lab02

### Data Types in C

**Submitted by:** Hannah Kelley

**Date of Experiment:** September 3, 2025

**Report Deadline:** September 10, 2025

**Demonstration Deadline:** September 10, 2025

## Theory

### Topic 1: Different Data Types

- a) In C programming data types determine the kind of value a variable can hold and how much memory is allocated for it. Integer values of various sizes can be stored in char, short, int, long, and long long variables. Decimal values can be stored in float and double variables. Each data type has two variations—signed and unsigned—which determine whether or not it can represent negative values. Declaring the correct data type is important for optimizing a program's efficiency and accuracy.

### Topic 2: Size Limit of Data Types

- a) In computer systems, the size of a data type is defined by the number of bytes it occupies in memory, which in turn determines the range of values it can store. For signed integer types, one bit is dedicated to representing the sign (positive or negative), reducing the maximum magnitude that can be expressed. In contrast, unsigned integer types use all bits to represent the magnitude, allowing for a greater range of positive values but excluding negative numbers. Floating-point types, such as float and double, are represented according to the IEEE 754 standard, which divides the available bits into a sign, an exponent, and a mantissa, with the specific allocation depending on the precision of the data type.

### Topic 3: Endianness

- a) Endianness refers to the way in which a computer stores and interprets data in memory. In little-endian systems, such as the one in this lab, the least significant byte is stored at the lowest memory address. In big-endian systems, the most significant is placed at the lowest memory address.

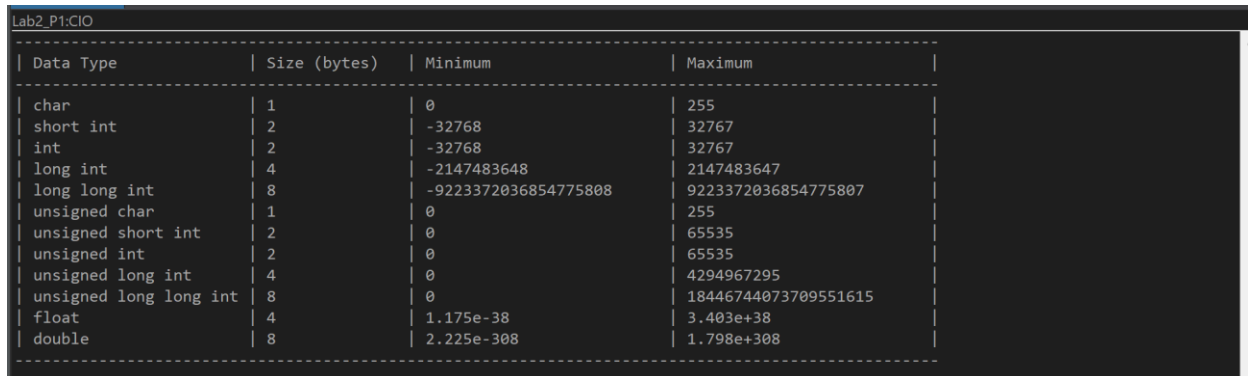

## Results & Observation

### Program 1:

#### Program Description:

This program prints the sizes and ranges of common C data types by using macros contained in the limits.h and float.h libraries. The results are displayed in a formatted table.

## Program Output:

```
Lab2_P1:CIO
-----
| Data Type          | Size (bytes) | Minimum          | Maximum          |
-----|-----|-----|-----|
| char               | 1            | 0                | 255              |
| short int          | 2            | -32768           | 32767            |
| int                | 2            | -32768           | 32767            |
| long int           | 4            | -2147483648      | 2147483647       |
| long long int      | 8            | -9223372036854775808 | 9223372036854775807 |
| unsigned char      | 1            | 0                | 255              |
| unsigned short int | 2            | 0                | 65535            |
| unsigned int       | 2            | 0                | 65535            |
| unsigned long int  | 4            | 0                | 4294967295       |
| unsigned long long int | 8          | 0                | 18446744073709551615 |
| float              | 4            | 1.175e-38        | 3.403e+38        |
| double             | 8            | 2.225e-308       | 1.798e+308       |
-----
```

## Report Questions:

### 1. How are format specifiers used in your Q1 program?

In this program, format specifiers are used with the printf function to correctly display values of different data types. Each data type requires its own specifier so that the stored value is interpreted and printed properly. By carefully selecting the correct format specifier, the program ensures that all sizes, minimums, and maximums for different data types are displayed in a clear and accurate way.

## Problem 2:

### Problem Description:

Manually calculate the maximum and minimum values for all 4-byte data types found in program 1.

### Problem Calculations:

The 4-byte data types identified in the output table of program 1 are signed and unsigned long ints and float. The table below summarizes the findings of this section.

Table 01: Data Type Maximum and Minimum Values

Data Type	Maximum Value	Minimum Value
Signed long int	2,147,483,647	-2,147,483,648
Unsigned long int	4,294,967,295	0
Float (32 bits)	$3.403 \times 10^{38}$	$1.175 \times 10^{-38}$

We know that the maximum value of a signed data type is  $2^{n-1} - 1$  and the minimum value is  $-2^{n-1}$  where n is the number of bits each data type has allocated. We subtract one from the exponent because the sign bit takes up the first bit of a number and cannot be used to represent the magnitude of the number. We subtract one from the maximum value because zero is represented as a positive number. Using these formulas we know the maximum value of a signed long int is  $2^{32-1} - 1 = 2,147,483,647$ . The minimum value is  $-2^{32-1} = -2,147,483,648$ .

For unsigned data types the maximum value is  $2^{n-1}$ . In this case we do not need to subtract one from the exponent since all the bits allocated for the value are used to store the value itself and not the sign. The maximum value of an unsigned long int is  $2^{32-1} = 4,294,967,295$ . The minimum value is zero.

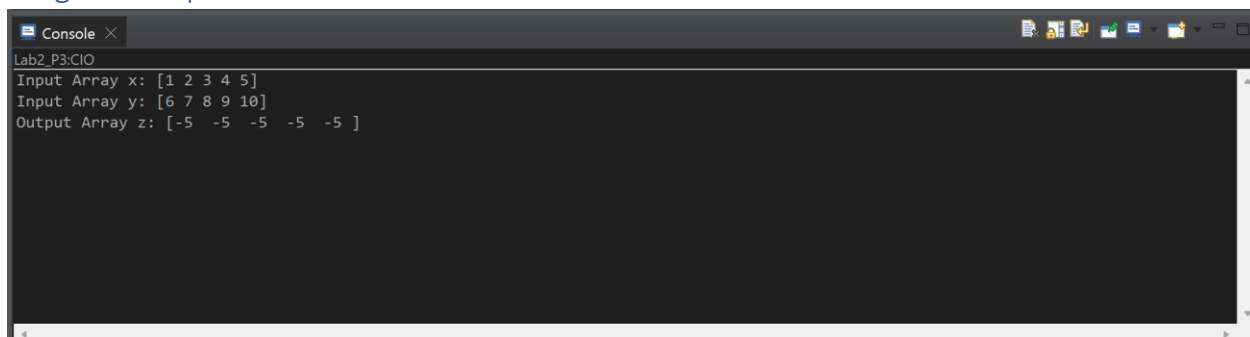

Floats are also known as single precision floating point numbers. From the IEEE-754 standard we know that 32 bit float use 1 bit to represent the sign, 8 bits to represent the exponent, and the remaining 23 bits to represent the mantissa. To get the highest possible number the sign bit will be 0 and the exponent bits will be 1111\_1110. The exponent value 1111\_1111 is reserved for special values like infinity and NaN. The largest possible mantissa will have 23 bits of all ones. Additionally, since all IEEE-754 numbers have an implicit leading 1 we have 24 bits of all ones. This will give us the largest 32 bit float number of  $(-1)^0(2^{127})(2 - 2^{-23}) = 3.408 \times 10^{38}$ . To get the lowest possible positive value the sign bit will be 1, the exponent will be 1, and the mantissa will be 1. This will give us the smallest positive 32 bit float number of  $(-1)^0(2^{-126})(1.0) = 1.175 \times 10^{-38}$ .

### Program 3:

#### Program Description:

This program declares and initializes two integer arrays, x and y, each containing at least five elements. It computes a third array where each element is the result of subtracting the corresponding element of y from x. The program then displays the input arrays and the resulting output array in a clear, formatted manner.

#### Program Output:

A screenshot of a console window titled 'Console' with a close button. The window shows the output of a program. The text displayed is: 'Lab2\_P3:CIO', 'Input Array x: [1 2 3 4 5]', 'Input Array y: [6 7 8 9 10]', and 'Output Array z: [-5 -5 -5 -5 -5 ]'. The console has a dark background and a light-colored text color. There are standard window controls (minimize, maximize, close) in the top right corner.

```
Console X
Lab2_P3:CIO
Input Array x: [1 2 3 4 5]
Input Array y: [6 7 8 9 10]
Output Array z: [-5 -5 -5 -5 -5 ]
```

Figure 02: Program 3 Output

#### Report Questions:

##### 1. How are you calculating the output matrix in Q3?

In this program the output matrix is calculated by looping through all three matrices at the same time. The subtraction is calculated index-by-index and then stored in the output matrix before moving on to the next loop iteration.

## Program Flowchart:
